

An Introduction to

# Mutation Testing and Metamorphic Testing

Luigi Libero Lucio Starace

`luigiliberolucio.starace@unina.it`

# Mutation Testing

What if I told you that you can start **killing mutants** to **test your tests**?

# Testing your tests

How do you know if your test suite is **effective** or not?

- I wrote clean tests that run in isolation with Hamcrest and Mockito!
  - That's great, but it doesn't tell much on the effectiveness of the test suite
- I practiced TDD, so everything is tested!
  - Are you *really really really really really* sure of their effectiveness?
- My tests cover 100% of the branches!
  - Not very indicative. Coverage is good at telling us which parts are never covered, but tells very little on **how well** the covered parts are tested!

# What is Mutation Testing?

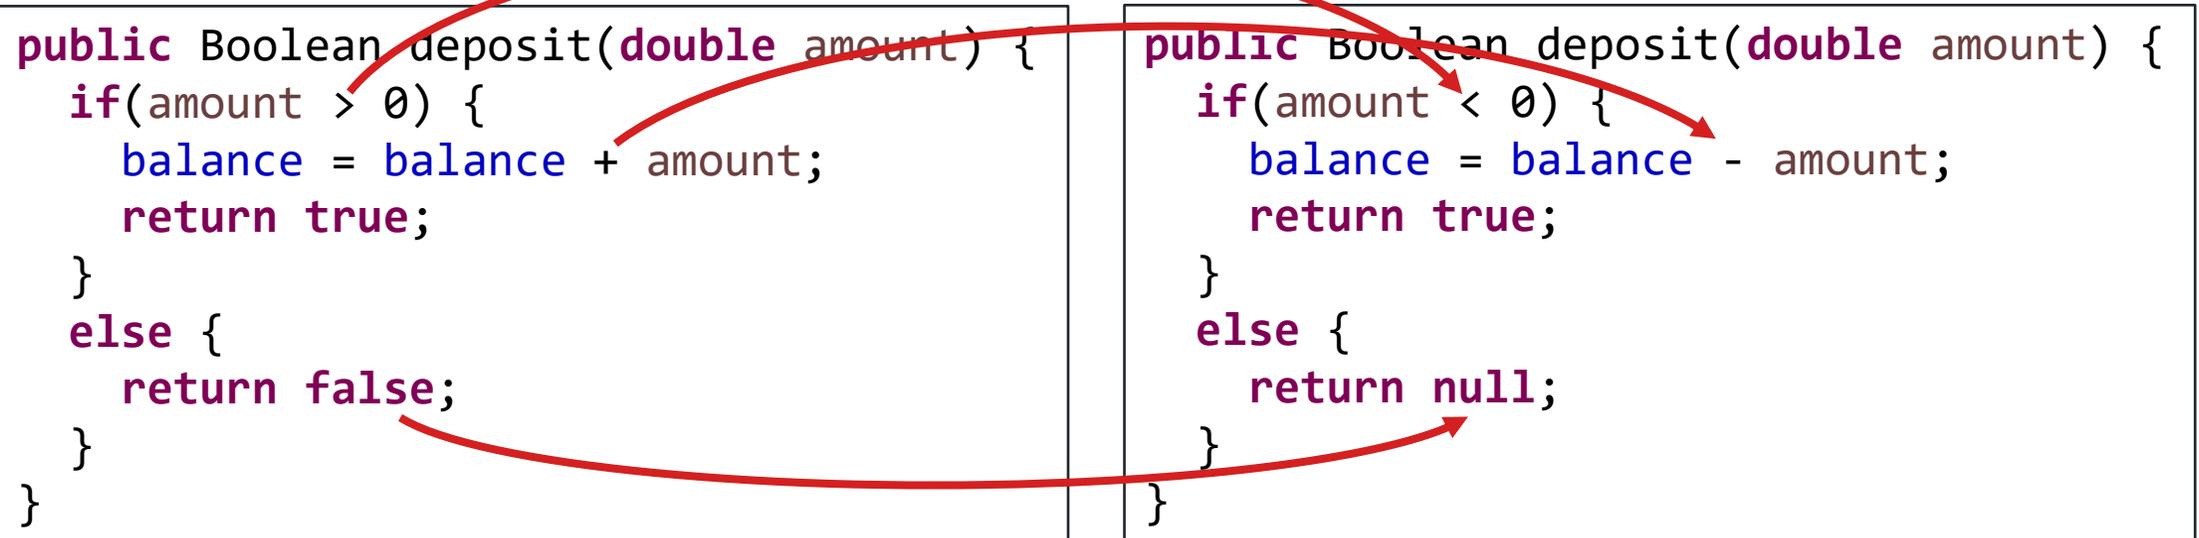

- Mutation Testing is a technique to **evaluate** the **effectiveness** of test suites.
- Let's start with some terminology

A Chitten, art from [gypporama.com](https://gypporama.com)

# Software Mutations

A software mutation is a **small** change in your codebase

# Software Mutants

- Don't have super powers or adamantium bones (luckily!)
- They're just **versions** of your software containing one or more mutations

# Mutation Testing

- You have your software, and a nice and shiny test suite
- Generate (**automatically**) a lot of mutants for your codebase
- Run (**a selection of**) your tests on each mutant
- See what happens:
  - If one of the test fails, we say that the mutant is **killed** by the test suite
  - If all the tests pass, the mutant **escapes**
  - Timeout (mutant introduced an infinite loop!)
- A **good** test suite is one that kills a lot of mutants!

# Not all mutants are bad

- An escaped mutant is not necessarily a bad thing
- Some mutants might be equivalent to the original
- Some might even happen to fix bugs in your code!

```
public boolean isSumZero(int[] array) {  
    int sum = 0;  
    for(int i : array)  
        sum = sum + i;  
    return sum == 0;  
}
```

Equivalent mutant

```
public boolean isSumZero(int[] array) {  
    int sum = 0;  
    for(int i : array)  
        sum = sum - i;  
    return sum == 0;  
}
```

# Challenges

**CPU intensive** and **time consuming** (can be parallelized)

- Suppose your codebase has 100 classes and 1000 tests
- Suppose a test runs, on average, in 0.1 seconds
- Suppose that you generate 10 mutants for each class.
- If we ran the entire test suite on each mutant, it would take

$$100 \cdot 10 \cdot 1000 \cdot 0.1 \text{ seconds} = 100\,000 \text{ seconds} \approx 28 \text{ hours}$$

**Test selection/prioritization** techniques come in handy!

# Mutation Testing in practice

- Infection (PHP) <https://infection.github.io/>
- Cosmic Ray (Python) <https://github.com/sixty-north/cosmic-ray>
- Stryker (JS, C#, Scala) <https://stryker-mutator.io/>
- PIT (Java) <https://pitest.org/>

# PITest

- State-of-the-art Java mutation testing system
- Insert mutations through bytecode manipulation
- Several optimization heuristics
  - Only runs tests covering the mutated lines
  - Interrupts tests taking too long
- Large set of [built-in mutators](#)
- Easy integration with build tools/IDEs/CI-CD
- Detailed and human-readable reports

# PIT demo

Let's kill some mutants

# Our codebase

```
public class SavingsAccount {
    private double balance;

    public SavingsAccount() { this.balance = 0; }

    public boolean deposit(double amount) {
        if(amount > 0) {
            this.balance = this.balance + amount;
            return true;
        }
        else {
            return false;
        }
    }
    /* ... */
}
```

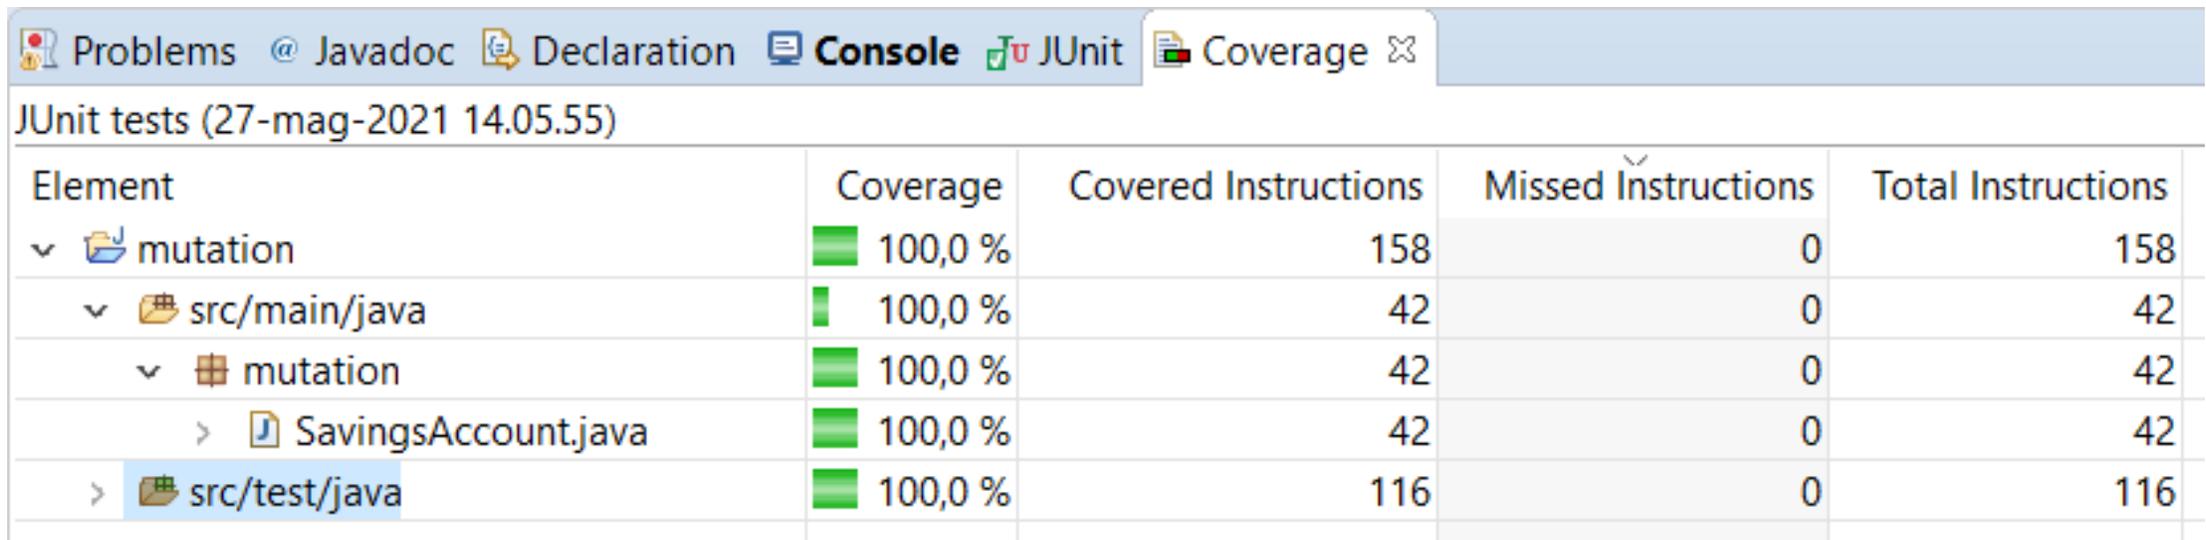

# Our codebase

```
@Test
@DisplayName("Should correctly deposit a positive amount")
void shouldDepositCorrectly() {
    SavingsAccount s = new SavingsAccount();
    boolean ret = s.deposit(42.0);
    assertThat(ret, is(true));
    assertThat(s.getBalance(), is(closeTo(42.0, 0.001)));
}
```

```
@Test
@DisplayName("Should not deposit negative amounts")
void shouldNotDepositNegativeAmounts() {
    SavingsAccount s = new SavingsAccount();
    boolean ret = s.deposit(-42.0);
    assertThat(ret, is(false));
    assertThat(s.getBalance(), is(closeTo(0.0, 0.001)));
}
```

# What about that test suite?

- Both the tests pass
- They get us to 100% statement (and branch!) coverage

The screenshot shows the Coverage tool in an IDE. The title bar includes 'Problems', 'Javadoc', 'Declaration', 'Console', 'JUnit', and 'Coverage'. The main area displays 'JUnit tests (27-mag-2021 14.05.55)'. Below this is a table with the following data:

Element	Coverage	Covered Instructions	Missed Instructions	Total Instructions
mutation	100,0 %	158	0	158
src/main/java	100,0 %	42	0	42
mutation	100,0 %	42	0	42
> SavingsAccount.java	100,0 %	42	0	42
> src/test/java	100,0 %	116	0	116

Is the test suite really **effective**, though?

# Let's try mutation testing with PIT

## Configure Maven to use the PIT plugin

```
<plugin> <!-- pom.xml file -->
  <groupId>org.pitest</groupId>
  <artifactId>pitest-maven</artifactId>
  <version>1.4.3</version>
  <!-- dependencies, executions... -->
  <configuration>
    <targetClasses>
      <param>mutation.*</param><!--mutate all classes in the mutation package-->
    </targetClasses>
    <targetTests>
      <param>mutation.*</param><!--consider only tests in the same package-->
    </targetTests>
  </configuration>
</plugin>
```

# Let's try mutation testing with PIT

## PIT execution

```
=====
- Timings
=====
> scan classpath : < 1 second
> coverage and dependency analysis : < 1 second
> build mutation tests : < 1 second
> run mutation analysis : < 1 second
-----
> Total   : 1 seconds
=====
- Statistics
=====
>> Generated 13 mutations Killed 10 (77%)
>> Ran 21 tests (1.62 tests per mutation)
```

# Let's try mutation testing with PIT

- PIT produces also a **detailed, human-readable HTML** report
- The report allows us to see which mutants were generated and which ones escaped

## Pit Test Coverage Report

### Package Summary

#### mutation

Number of Classes	Line Coverage	Mutation Coverage
1	100%  12/12	77%  10/13

### Breakdown by Class

Name	Line Coverage	Mutation Coverage
<a href="#">SavingsAccount.java</a>	100%  12/12	77%  10/13

Report generated by [PIT](#) 1.4.3

# Reading PIT reports

- The blue numbers indicate how many mutants were generated by modifying the corresponding line (e.g.: 2 mutants for line 14)
- Red lines are those for which at least one of the corresponding mutants escaped
- Every mutant for the green lines was killed

```
13 public boolean deposit(double amount) {
14 2 if(amount > 0) {
15 1 this.balance = this.balance + amount;
16 1 return true;
17 }
18 else {
19 1 return false;
20 }
21 }
```

# Reading PIT reports

- PIT also tells us which mutation operators were applied on each line

1. deposit : changed conditional boundary → SURVIVED (i.e.: changed > with >= )  
2. deposit : negated conditional → KILLED (i.e.: changed > with <= )

```
13 public boolean deposit(double amount) {  
14 2  if(amount > 0) {  
15 1  this.balance = this.balance + amount;  
16 1  return true;  
17  }  
18  else {  
19 1  return false;  
20  }  
21 }
```

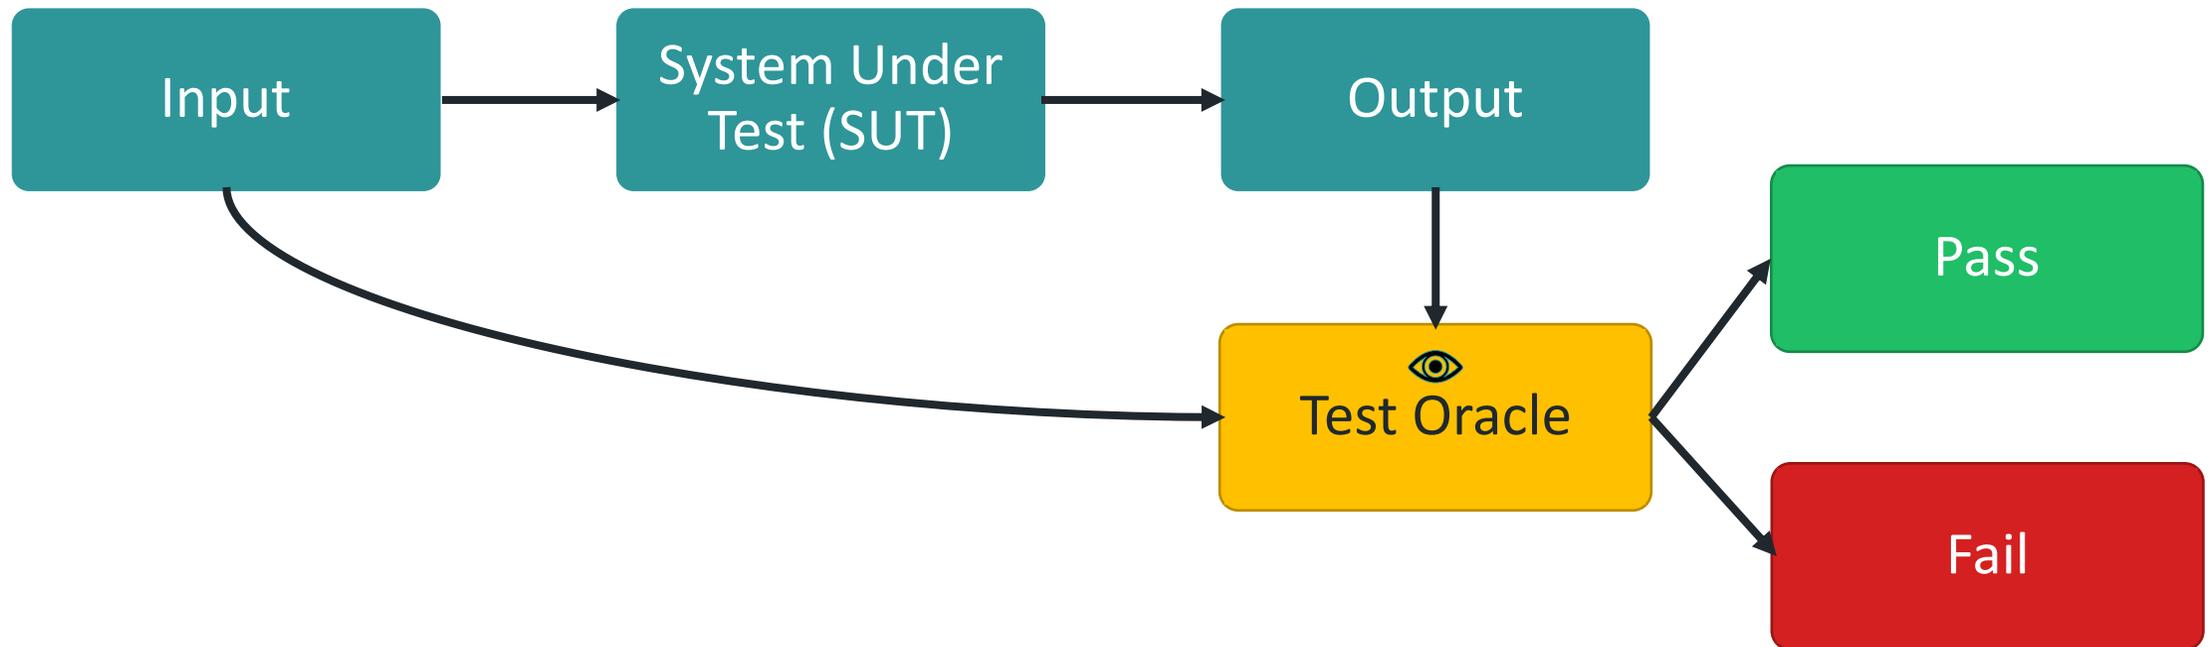

The mutant escaped because we did not properly test boundary values. **What happens when we try to withdraw zero money?**

# Metamorphic Testing

Solving the oracle problem, one metamorphosis at a time

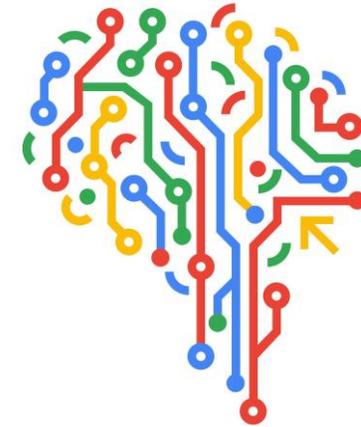

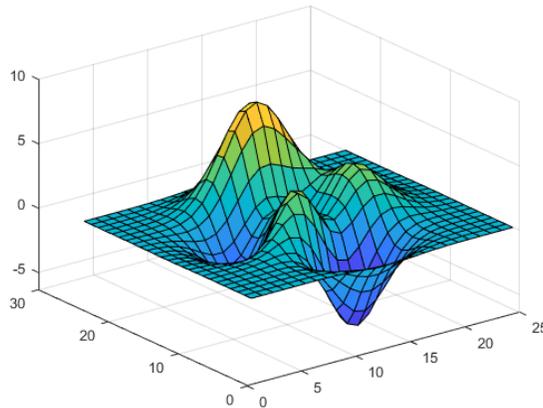

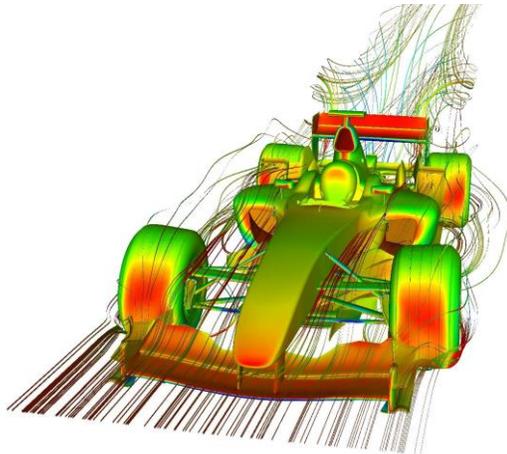

# Test oracles

- A **test oracle** is a mechanism to decide whether a test output is correct

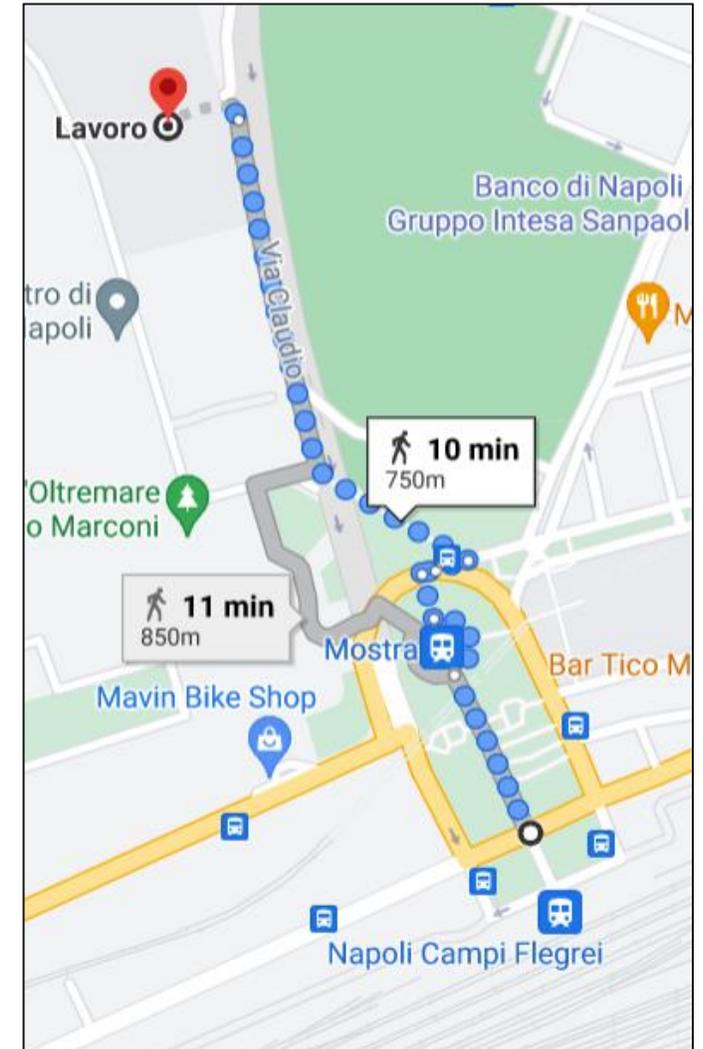

# The oracle problem

- Sometimes it's not feasible to get an automated test oracle
- This is an issue especially when trying to **automatically generate** tests

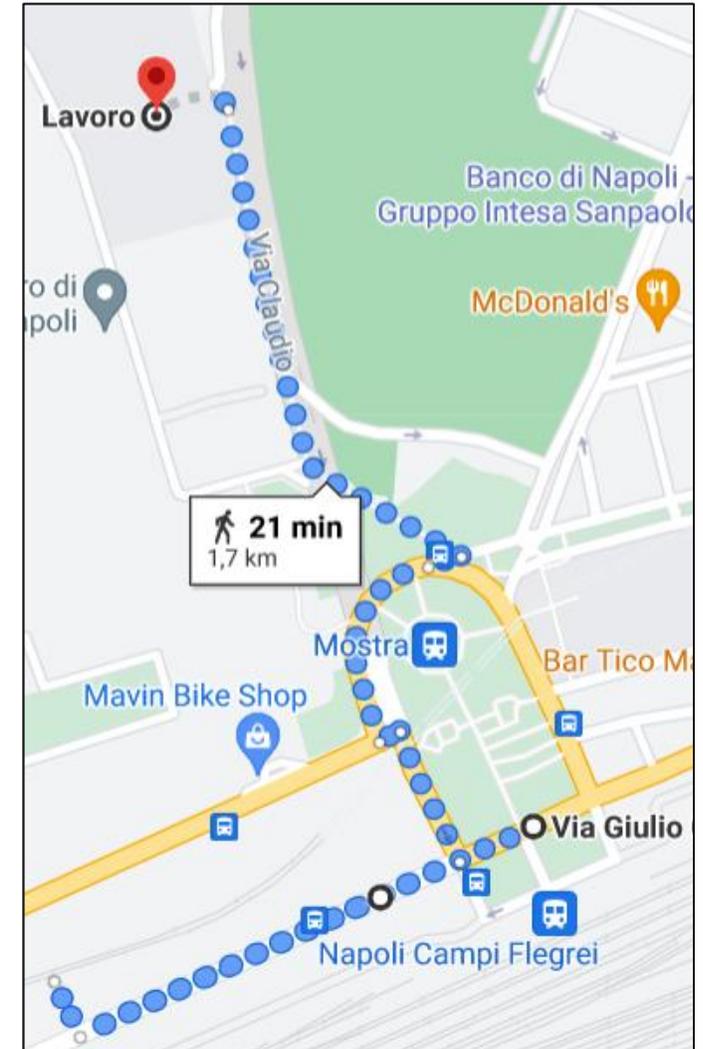

# Metamorphic Testing by example (Maps)

- Suppose you're an automated testing tool
- Your task is to test the Google Maps app
- You start with a first query...
- Is the result correct?
- Hard to tell for an automatic tool!

# Metamorphic Testing by example (Maps)

- You can try a slightly different query
- The starting point is moved 10 meters west this time
- It is reasonable to expect the proposed path to be roughly the same
- Otherwise, it is likely that there's a bug in the system!

# Metamorphic Testing by example (Search)

- Suppose you're testing a search engine-like application
- You get 39 results matching your initial query

The screenshot shows a travel search interface. At the top, there are search filters: "Bora Bora, Leeward Islands, French Polynesia", "Mon 8/9", and "Sun 8/22". Below the filters, there are 39 results out of 108 properties. The first result is "InterContinental Bora Bora Resort and Thalasso Spa". The card for this resort includes a "Book now" button, a "Go to map" button, a "Recommended filters" section, a "Stars" section with 5 stars, a "Price trend: Rising" indicator, a price of "\$962" from "Booking.com", and a "Free WiFi" feature. There is also a "View Deal" button. The resort's rating is 9.2 (Excellent) based on 75 reviews. The location is Vaitape, Bora Bora, French Polynesia. The price is shown for Orbitz (\$963), Hotels.com (\$963), travelup (\$989), and 11 more sites (\$960).

# Metamorphic Testing by example (Search)

- If you restrict your search (e.g.: consider only 5 star structures)
- You expect to get a subset of the initial set of hotels!

The screenshot shows a search interface for hotels in Bora Bora, French Polynesia. The search parameters are set to "Bora Bora, Leeward Islands, French Polynesia" with dates from Monday 8/9 to Sunday 8/22. The results are sorted by "Recommended" and show 4 of 108 properties. A "Go to map" button is visible. The "Recommended filters" section includes a "Stars" filter with 5 stars selected. The main result is for "Four Seasons Resort Bora Bora", which has a 9.4 rating (Excellent) based on 114 reviews. The price is \$1,596 per night, with a "View Deal" button. The location is Vaitape, Bora Bora, French Polynesia. Other booking options are shown for Hotels.com (\$1,596) and KAYAK (\$1,630). The deal includes free breakfast and free cancellation.

# The intuition behind Metamorphic Testing

- Sometimes, we do not know whether the output of any individual input is correct
- **But**, we may know the relation between some inputs and their outputs!

# Metamorphic Testing

- Identify some meaningful properties of the problem (the so-called **metamorphic relations**)
- Define a **source** (initial) test case
- Generate **follow-up** test cases by using the metamorphic relations to transform the **source** input and validate the output.

# Successful applications

Metamorphic testing has been applied with promising results in many different scenarios (in addition to the one we already talked about!):

- Compilers and Graphic Drivers
- Cybersecurity (e.g. code obfuscators)
- Bioinformatics and numerical programs
- Machine Learning applications
- Autonomous driving
- ... and many more!
